MULTIFRACTAL ANALYSIS IN A MIXED ASYMPTOTIC FRAMEWORK

By Emmanuel Bacry , Arnaud Gloter, Marc Hoffmann
and Jean François Muzy

Ecole Polytechnique, Université Paris-Est and Université de Corse

Multifractal analysis of multiplicative random cascades is revisited within the framework of *mixed asymptotics*. In this new framework, statistics are estimated over a sample which size increases as the resolution scale (or the sampling period) becomes finer. This allows one to continuously interpolate between the situation where one studies a single cascade sample at arbitrary fine scales and where at fixed scale, the sample length (number of cascades realizations) becomes infinite. We show that scaling exponents of "mixed" partitions functions i.e., the estimator of the cumulant generating function of the cascade generator distribution, depends on some "mixed asymptotic" exponent χ respectively above and beyond two critical value p_χ^- and p_χ^+. We study the convergence properties of partition functions in mixed asymtotics regime and establish a central limit theorem. These results are shown to remain valid within a general wavelet analysis framework. Their interpretation in terms of Besov frontier are discussed. Moreover, within the mixed asymptotic framework, we establish a "box-counting" multifractal formalism that can be seen as a rigorous formulation of Mandelbrot's negative dimension theory. Numerical illustrations of our purpose on specific examples are also provided.

1. Introduction.

Multifractal processes have been used successfully in many applications which involve series with invariance scaling properties. Well known examples are fully developed turbulence where such processes are used to model the velocity or the dissipation energy fields [6] or finance, where they have been shown to reproduce very accurately the major "stylized facts" of return time-series [4, 5, 21]. Since pioneering works of Mandelbrot [14, 15], Kahane and Peyrière [11], a lot of mathematical studies have been devoted to multiplicative cascades, denoted in sequel as $\mathcal{M}$-cascades (see e.g. refs [8, 13, 18, 22]). One of the central issues of these studies was to understand how the partition function scaling exponents (hereafter denoted as $\tau_0(q)$), are related, on one hand, to the cumulant generating function of cascade weight distribution and, on the other hand, to the regularity properties of cascade samples. Actually, the goal of the multifractal formalism is to directly relate the function $\tau_0(q)$ to the so-called singularity spectrum, i.e., the Hausdorff dimension of the set of all the points corresponding to given Hölder exponent. Let us mention that recently continuous versions of multiplicative cascades have been introduced [1, 2] : they share most of properties with discrete cascades but do not involve any preferential scale ratio and remain invariant under time translation. In these constructions, the analog of the integral scale T, i.e., the coarsest scale where the cascade iteration begins, is a correlation time.

In all the above cited references, the main results concern one single cascade over one integral scale T in the limit of arbitrary small sampling scale. However, in many applications (e.g., the above turbulence experiments) there is no reason a priori that the length of the experimental series corresponds to one (or few) integral scale(s). From a general point of view, as long as modeling a discrete (time or space) series with a cascade process is concerned, three scales are involved : (i) the resolution scale l which corresponds to the sampling period of the series, (ii) the *integral (or correlation) scale* T and (iii) the size L of the whole series. Using these notations, the total number of samples of the series is

$$N = \frac{L}{l}.$$

Therefore, when modeling a discrete series with a multifractal process, various types of asymptotics for $N \to +\infty$ can be defined. The "high resolution asymptotics" considered in the literature, corresponds to $l \to 0$ whereas L is fixed. On the other side, one could also consider the "infinite historic asymptotics" that corresponds to $L \to +\infty$ whereas l is fixed. If we define N_T to be the number of integral scales involved in the series

$$N_T = \frac{L}{T},$$

and N_l the number of samples per integral scale

$$N_l = \frac{T}{l}, \tag{1}$$

then we have

$$N = N_T N_l.$$

Thus, the high resolution asymptotics corresponds to N_T fixed and $N_l \to +\infty$ whereas the infinite historic asymptotics corresponds to N_l fixed and $N_T \to +\infty$. But in many applications, it is clear that since the relative values of N_T and N_l can be arbitrary, it is not obvious that one of the two mentionned asymptotics can account suitably for situation. This leads us to consider an asymptotics according to which N_T and N_l go to infinity (and therefore N goes to infinity) and at the same time preserve their relative "velocities", i.e., the ratio of their logarithm. Some of us, have already suggested the following "mixed asymptotics" [12, 19, 20] :

$$N_T = N_l^{\chi},$$

where $\chi \in \mathbb{R}^+$ is a fixed number that quantifies the relative velocities of N_T and N_l. Thus,

- $\chi = 0$ corresponds to the high resolution asymptotics,
- $\chi \to +\infty$ corresponds to the infinite historic asymptotics,

and all other values are truly "mixed" asymptotics. Successful applications of the mixed asymptotics have already been performed [19, 20]. In this paper we revisit the standard problems of (i) the estimation of cascade generator cumulant generating function in the mixed asymptotic framework and of (ii) the multifractal formalism or of how to relate this function to a dimension-like quantity.

The paper is organized as follows: in section 2 we recall basic definitions and properties of $\mathcal{M}$-cascades. Section 3 contains the main results of this paper. If we define a multifractal measure $\tilde{\mu}$ as the concatenation of independent $\mathcal{M}$-cascades of length T, with common generator law W, then we show in Theorem 2:

$$\frac{1}{\log(1/l)} \log\left(N^{-1}\sum_{k=0}^{N-1} \tilde{\mu}\left([kl,(k+1)l]\right)^p\right) \to p - \log_2 E[W^p] := \tau(p) + 1$$

for p in some range (p_χ^-, p_χ^+). These critical exponents p_χ^-, p_χ^+ are related to the two solutions, h_χ^-, h_χ^+ of the equation $D(h) = -\chi$ where

$$D(h) = \inf_p \{ph - \tau(p)\}$$

is the Legendre transform of τ. The convergence rate is studied in Section 3.5. Let us stress that the range of validity on p of this convergence is wider in the mixed asymptotic framework ($\chi > 0$) than in the high resolution asymptotic ($\chi = 0$). As a consequence we can relate $D(h)$ to a "box-counting dimension" (sometimes referred to as a box dimension [10] or a coarse-grain spectrum [24]), and derive, as stated in Theorem 4, a "box-counting multifractal formalism" for $\tilde{\mu}$

$$\frac{1}{N_T}\#\{k \in \{0,\dots,N\} \mid \tilde{\mu}\left([kl,(k+1)l]\right) \in [l^{h-\varepsilon}, l^{h+\varepsilon}]\} \simeq l^{-D(h)}$$

in the range of $[h_\chi^+, h_\chi^-]$. Since for $\chi > 0$, $D(h)$ can take negative values in previous equation, this can be seen as a rigorous formulation of Mandelbrot's negative dimension theory [16, 17]. In section 4, we extend previous results to partition functions relying on some arbitrary wavelet decomposition of the process. In Section 5 we give an interpretation of the results connected with the Besov frontier associated with our multifractal measure. Finally, in section 6 we discuss some specific examples where the law of the cascade generator is respectively log-normal, log-Poisson and log-Gamma. For illustration purpose, we also report, in each case, estimations performed from numerical simulations. Auxiliary useful Lemmas are moved to Appendices.

2. $\mathcal{M}$-cascades : Definitions and properties.

2.1. *Definition of the $\mathcal{M}$-cascades.* Let us first introduce some notations. Given a j-uplet $r = (r_1, \ldots, r_j)$, for all strictly positive integer $i \leq j$, we note $r|i$ the restriction of the j-uplet to its first i components, i.e.,

$$r|i = (r_1, \ldots, r_i), \quad \forall i \in \{1, \ldots, j\}.$$

By convention, if $j = 0$, we consider that $r = \emptyset$ and in the sequel, we denote by rr' the $j + j'$-uplet obtained by concatenation of $r \in \{0,1\}^j$ and $r' \in \{0,1\}^{j'}$. Moreover, we note

$$\overline{r} = \begin{cases} 2^j \sum_{i=1}^{j} r_i 2^{-i}, & \text{if } r \neq \emptyset \\ 0 & \text{if } r = \emptyset \end{cases} .$$

Let fix $T \in \mathbb{R}^{+*}$ and $k \in \mathbb{N}$. We define $I_{j,k}$ as the interval

$$I_{j,k} = [k2^{-j}T, (k+1)2^{-j}T]. \tag{2}$$

Thus, for any $j \in \mathbb{N}^*$, the interval $[0, T]$ can be decomposed as 2^j dyadic intervals :

$$[0, T] = \bigcup_{r \in \{0,1\}^j} I_{j,\overline{r}}.$$

Let us now build the so called $\mathcal{M}$-cascade measures introduced by Mandelbrot in 1974 [15]. Let $\{W_r\}_{r \in \{0,1\}^j,\ j \in \mathbb{N}^*}$ be a set of i.i.d random variables of mean $\mathbb{E}[W_r] = 1$. Given $j \in \mathbb{N}^*$, we define the random measure μ_j on $[0, T]$ such that, for all $r \in \{0,1\}^j$, the Radon-Nikodym derivative with respect to the Lebesgue measure $\frac{\mathrm{d}\mu_j}{\mathrm{d}x}$ is constant on $I_{j,\overline{r}}$ with:

$$\frac{\mathrm{d}\mu_j}{\mathrm{d}x} = \prod_{i=1}^{j} W_{r|i}, \quad \text{on } I_{j,\overline{r}}, \text{ for } r \in \{0,1\}^j. \tag{3}$$

As it is well known [11], the measures μ_j have a non-trivial limit measure μ_∞, when j goes to ∞, as soon as $\mathbb{E}\left[W \log_2 W\right] < 1$. Moreover, the total mass

$$\mu_\infty\left([0,T]\right) = \lim_{j\to\infty} T2^{-j} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} W_{r|i},$$

verifies $\mathbb{E}\left[\mu_\infty\left([0,T]\right)\right] = T$. Let us remark that if $r \in \{0,1\}^j$ then by construction we have:

$$\begin{aligned} \mu_\infty(I_{j,\overline{r}}) &= \lim_{n\to\infty} T2^{-j} \prod_{i=1}^{j} W_{r|i} \left(\sum_{r'\in\{0,1\}^n} 2^{-n} \prod_{i=1}^{n} W_{rr'|(j+i)} \right) \\ &= 2^{-j} \left(\prod_{i=1}^{j} W_{r|i} \right) \overline{\mu}_\infty^{(r)}\left([0,T]\right), \qquad (4) \end{aligned}$$

where $\overline{\mu}_\infty^{(r)}$ is a $\mathcal{M}$-cascade measure on $[0,T]$ based on the random variables $W_{rr'}$ for $r' \in \cup_{j\geq 1}\{0,1\}^j$. This equality is usually referred to as "Mandelbrot star equation".

In the sequel we need the following set of assumptions:

$$\mathbb{E}\left[W \log_2 W\right] < 1, \;\; \mathbb{P}(W=1) < 1, \qquad (5)$$

$$\mathbb{P}(W>0) = 1, \;\; \mathbb{E}\left[W^p\right] < \infty \text{ for all } p \in \mathbb{R}. \qquad (6)$$

Let $\tau(p)$ be the smooth and concave function defined on $\mathbb{R}$ by

$$\tau(p) = p - \log_2 \mathbb{E}\left[W^p\right] - 1. \qquad (7)$$

Let us notice that $\log_2 \mathbb{E}\left[W^p\right]$ is nothing but the cumulant generating function (log-Laplace transform) of the logarithm of cascade generator distribution. It is shown in [11] that for $p > 1$, the condition $\tau(p) > 0$ implies the finiteness of $\mathbb{E}\left[\mu_\infty\left([0,T]\right)^p\right]$. By Theorem 4 in [18], the conditions (6) imply the existence of finite negative moments $\mathbb{E}\left[\mu_\infty\left([0,T]\right)^p\right]$, for all $p < 0$.

2.2. *Multifractal properties of $\mathcal{M}$-cascades.* A M-cascade is a multifractal measure and the study of its multifractal properties reduces to the study of the *partition function*

$$\mathcal{S}_\mu(j,p) = \sum_{k=0}^{2^j-1} \mu_\infty(I_{j,k})^p. \qquad (8)$$

Basically, one can show [18, 22] that, for fixed p, this partition function behaves, when j goes to ∞, as a power law function of the scale $|I_{j,k}| = T2^{-j}$.

More precisely, let us introduce the two following critical exponents:

$$\begin{aligned} p_0^+ &= \inf\{p \geq 1 \mid p\tau'(p) - \tau(p) \leq 0\} \in (1, \infty] \\ p_0^- &= \sup\{p \leq 0 \mid p\tau'(p) - \tau(p) \leq 0\} \in [-\infty, 0). \end{aligned}$$

If p_0^+ (resp. p_0^-) is finite we set $h_0^+ = \tau'(p_0^+)$ (resp. $h_0^- = \tau'(p_0^-)$).

THEOREM 1. **Scaling of the partition function** *[22]*
Let $p \in \mathbb{R}$, the power law scaling exponent of $\mathcal{S}_\mu(j,p)$ is given by

$$\lim_{j\to\infty} \frac{\log_2 \mathcal{S}_\mu(j,p)}{-j} \xrightarrow[a.s.]{} \tau_0(p), \tag{9}$$

where $\tau_0(p)$ is defined by

$$\tau_0(p) = \begin{cases} \tau(p), & \forall p \in (p_0^-, p_0^+) \\ h_0^+ p, & \forall p \geq p_0^+ \\ h_0^- p, & \forall p \leq p_0^- \end{cases} . \tag{10}$$

The proof can be found in [22]. The convergence in probability of (9) was obtained in the earlier work [18]. This theorem basically states that $\mathcal{S}_\mu(j,p)$ behaves like

$$\mathcal{S}_\mu(j,p) \simeq 2^{-j\tau_0(p)}.$$

Let us note that the partition function (8) can be rewritten in the following way

$$\mathcal{S}_\mu(j,p) = \sum_{r\in\{0,1\}^j} \mu_\infty(I_{j,\overline{r}})^p \tag{11}$$

and using (4), one gets

$$\mathcal{S}_\mu(j,p) = 2^{-jp} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} W_{r|i}^p \left(\bar{\mu}_\infty^{(r)}([0,T])\right)^p, \tag{12}$$

where the $\{\bar{\mu}_\infty^{(r)}([0,T])\}_{r\in\{0,1\}^j}$ are i.i.d. random variables with the same law as $\mu_\infty([0,T])$. Thus, a simple computation shows that

$$\mathbb{E}\left[\mathcal{S}_\mu(j,p)\right] = 2^{-jp} 2^j \mathbb{E}\left[W^p\right]^j \mathbb{E}\left[\mu_\infty([0,T])^p\right] = 2^{-j\tau(p)} \mathbb{E}\left[\mu_\infty([0,T])^p\right].$$

One sees that the last theorem states that, in the case $p \in [p_0^-, p_0^+]$, $\mathcal{S}_\mu(j,p)$ scales as its mean value.

On the other hand, the fact that for $p \notin [p_0^-, p_0^+]$ the partition function scales as given in (10) instead of scaling as its mean value, is referred to as the 'linearization effect'. A possible explanation of this effect is that for p larger than the critical exponents p_0^+ (resp. smaller than p_0^-), the sum involved in the partition function (11) is dominated by its supremum (resp. infimum) term. Thus one should not expect a law of large number to hold for the behavior of this sum. Another possible interpretation of this theorem in the case $p > p_0^+$ is given in Section 5.

3. Mixed asymptotics for $\mathcal{M}$-cascades.

3.1. *Mixed asymptotics : definitions and notations.* A convenient way to construct a multifractal measure on $\mathbb{R}_+$, with an integral scale equal to T, is to patch independent realizations of $\mathcal{M}$-cascades measures. More precisely, consider $\{\mu_\infty^{(m)}\}_{m\in\mathbb{N}}$ a sequence of i.i.d $\mathcal{M}$-cascades on $[0,T]$ as defined in Section 2.1 and define the stochastic measure on $[0,\infty)$ by:

$$\tilde{\mu}\left([t_1,t_2]\right) = \sum_{m=0}^{+\infty} \mu_\infty^{(m)}\left([t_1 - mT, t_2 - mT]\right), \qquad \text{for all } 0 \leq t_1 \leq t_2. \tag{13}$$

This model is entirely defined as soon as both T and the law of W are fixed. The discretized time model for the N samples of the series is $\{\tilde{\mu}[kl,(k+1)l]\}_{0\leq k<N-1}$.

3.2. *Scaling properties.* In this section, we study the partition function for the measure $\tilde{\mu}$ as defined in Eq. (13) in the mixed asymptotic limit. T is fixed, we choose the sampling step

$$l = T2^{-j},\ N_l = 2^j,$$

and the number of integral scales is related with the sampling step as

$$N_T = \lfloor N_l^\chi \rfloor \sim 2^{j\chi},$$

with $\chi > 0$ fixed. According to (1), one gets for the total number of data:

$$N = N_T 2^j \sim 2^{j(1+\chi)}.$$

The mixed asymptotics corresponds to the limit $j \to +\infty$. The partition function of $\tilde{\mu}$ can be written as (recall (2)):

$$\mathcal{S}_{\tilde{\mu}}(j,p) = \sum_{k=0}^{N-1} \tilde{\mu}(I_{j,k})^p \tag{14}$$

$$= \sum_{m=0}^{N_T-1} \mathcal{S}_\mu^{(m)}(j,p), \tag{15}$$

where $\mathcal{S}_\mu^{(m)}(j,p)$ is the partition function of $\mu_\infty^{(m)}$, i.e.,

$$\mathcal{S}_\mu^{(m)}(j,p) = \sum_{k=0}^{2^j-1} \mu_\infty^{(m)}(I_{j,k})^p. \tag{16}$$

Let us state the results of this section. We introduce the two critical exponents in the mixed asymptotic framework:

$$p_\chi^+ = \inf\{p \geq 1 \mid p\tau'(p) - \tau(p) \leq -\chi\} \in (1,\infty] \tag{17}$$

$$p_\chi^- = \sup\{p \leq 0 \mid p\tau'(p) - \tau(p) \leq -\chi\} \in [-\infty,0), \tag{18}$$

and we set when these critical exponents are finite $h_\chi^+ = \tau'(p_\chi^+)$, $h_\chi^- = \tau'(p_\chi^-)$.

Theorem 2. **Scaling of the partition function in a mixed asymptotics**
Let $p \in \mathbb{R}$ and $\tilde{\mu}$ be the random measure defined by (13) *where the law of W satisfies* (5)*–*(6)*. We assume that, either $p_\chi^+ = \infty$, or $p_\chi^+ < \infty$ with $\tau(p_\chi^+) > 0$. Then, the power law scaling of $\mathcal{S}_{\tilde{\mu}}(j,p)$ is given by*

$$\lim_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu}}(j,p)}{-j} \xrightarrow[a.s.]{} \tau_\chi(p), \tag{19}$$

where $\tau_\chi(p)$ is defined by

$$\tau_\chi(p) = \begin{cases} \tau(p) - \chi, & \forall p \in (p_\chi^-, p_\chi^+) \\ h_\chi^+ p, & \forall p \geq p_\chi^+ \\ h_\chi^- p, & \forall p \leq p_\chi^- \end{cases}.$$

Remark 1. *If $p_\chi^+ = \infty$ then simple considerations on the concave function τ shows that $\tau(p) > 0$ for all $p > 1$, and hence the cascade measure has finite moments of any positive orders. Otherwise the assumption $\tau(p_\chi^+) > 0$ is stated in Theorem 2 to insure $\mathbb{E}\left[\mu_\infty([0,T])^p\right] < \infty$ for $p \in [0, p_\chi^+)$. Such assumption was not needed in Theorem 1, since on can check that necessarily $\tau(p_0^+) > 0$.*

Remark 2. *Let us stress that the behavior of the partition function is largely affected by the choice of a mixed asymptotic: the 'linearization effect' now occurs for p in the set $(-\infty, p_\chi^-) \cup (p_\chi^+, \infty)$, which is smaller when χ increases.*

Theorem 3. **Scaling of the supremum and the infimum of the mass in a mixed asymptotics**
Assume (5)–(6). *Then, if* $p_\chi^+ < \infty$, *one has,*

$$\lim_{j\to+\infty} \frac{\log_2 \sup_{k\in[0,N-1]} \tilde{\mu}(I_{j,k})}{-j} = h_\chi^+, \text{ almost surely,} \tag{20}$$

and if $p_\chi^- > -\infty$, *one has,*

$$\lim_{j\to+\infty} \frac{\log_2 \inf_{k\in[0,N-1]} \tilde{\mu}(I_{j,k})}{-j} = h_\chi^-, \text{ almost surely.} \tag{21}$$

The theorem 3 shows that when the 'linearization effect' occurs, the scaling of the partition function (14) is governed by its supremum and infimum terms for respectively large positive and negative p values.

These theorems will be proved in three parts. In Section 3.3.2, we will prove Eq. (19) of Theorem 2 only for $p \in (p_\chi^-, p_\chi^+)$. In Section 3.3.3, we will prove the case $p \notin (p_\chi^-, p_\chi^+)$ and Theorem 3 is shown in Section 3.3.4 to be a simple corrolary of this last case.

3.3. *Proof of Theorem 2.* First we need an auxiliary result which is helpful in the sequel.

3.3.1. *Limit theorem for a rescaled cascade.* For each m we denote as $(W_r^{(m)})_{r\in\cup_j\{0,1\}^j}$ the set of i.i.d. random variables used for the construction of the measure $\mu_\infty^{(m)}$. Moreover we assume that for each $m \geq 0$, $j \geq 0$, $r \in \{0,1\}^j$ we are given a random variable $Z^{(m,r)}$, measurable with respect to the sigma-field $\sigma\left(W_{rr'}^{(m)} \mid r' \in \cup_j\{0,1\}^j\right)$. We make the assumption that the law of $Z^{(m,r)}$ does not depend on (m,r), and denote by Z a variable with this law.

Let us consider the quantities, for $p \in \mathbb{R}$:

$$\mathcal{M}_j^{(m)}(p) = 2^{-jp} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} \left(W_{r|i}^{(m)}\right)^p Z^{(m,r)}, \tag{22}$$

and

$$\mathcal{N}_j(p) = \sum_{m=0}^{N_T-1} \mathcal{M}_j^{(m)}(p). \tag{23}$$

Proposition 1. *Assume that for some* $\epsilon > 0$, $\mathbb{E}\left[|Z|^{1+\epsilon}\right] < \infty$ *and* $-p\tau'(p) + \tau(p) < \chi$, *then:*

$$2^{j(\tau(p)-\chi)}\mathcal{N}_j(p) \xrightarrow{j\to\infty} \mathbb{E}[Z], \text{ almost surely.}$$

Proof. From (22)–(23) and the definition (7) we get,

$$\begin{aligned}\mathbb{E}[\mathcal{N}_j(p)] &= N_T 2^j 2^{-jp}\mathbb{E}[W^p]^j\,\mathbb{E}[Z] \\ &\sim_{j\to\infty} 2^{j\chi}2^{-j\tau(p)}\mathbb{E}[Z].\end{aligned}$$

Hence the proposition will be proved if we show:

$$2^{j(\tau(p)-\chi)}\left(\mathcal{N}_j(p) - \mathbb{E}[\mathcal{N}_j(p)]\right) \xrightarrow{j\to\infty} 0, \text{ almost surely.} \tag{24}$$

For an arbitrary small $\epsilon > 0$, we study the $L^{1+\epsilon}(\mathbb{P})$ norm of the difference. Set,

$$L_N^{1+\epsilon} = \mathbb{E}\left[|\mathcal{N}_j(p) - \mathbb{E}[\mathcal{N}_j(p)]\,|^{1+\epsilon}\right]. \tag{25}$$

Applying successively lemmas 1 and 2 of Appendix A, we get:

$$\begin{aligned}L_N^{1+\epsilon} &\le C2^{j\chi}\mathbb{E}\left[\left|\mathcal{M}_j^{(0)}(p)\right|^{1+\epsilon}\right] \\ &\le C2^{-j[(1+\epsilon)\tau(p)-\chi]}\sum_{k=0}^{j}2^{-k\tau(p(1+\epsilon))}2^{k(1+\epsilon)\tau(p)}.\end{aligned}$$

We deduce that $2^{j(\tau(p)-\chi)(1+\epsilon)}L_N^{1+\epsilon}$ is bounded by the quantity:

$$C2^{-j\chi\epsilon}\sum_{k=0}^{j}2^{-k\tau(p(1+\epsilon))}2^{k(1+\epsilon)\tau(p)}.$$

Clearly, as soon as $2^{-\chi\epsilon}2^{-\tau(p(1+\epsilon))}2^{(1+\epsilon)\tau(p)} < 1$, this quantity is, in turn, bounded by $C2^{-j\chi\epsilon'}$ for some $\epsilon' > 0$. Taking the log, a sufficient condition is

$$\frac{\tau(p)(1+\epsilon) - \tau(p(1+\epsilon))}{\epsilon} < \chi$$

which is implied for ϵ small enough by

$$-p\tau'(p) + \tau(p) < \chi.$$

Thus we have shown that $2^{j(\tau(p)-\chi)(1+\epsilon)}L_N^{1+\epsilon}$ is asymptotically smaller than $2^{-j\epsilon'}$ with some $\epsilon' > 0$. Using the Bienaymé-Chebyshev inequality leads to

$$\mathbb{P}\{2^{j(\tau(p)-\chi)}|\mathcal{N}_j(p) - \mathbb{E}[\mathcal{N}_j(p)]\,| \ge \eta\} \le \frac{2^{j(\tau(p)-\chi)(1+\epsilon)}L_N^{1+\epsilon}}{\eta^{1+\epsilon}} \le \frac{C2^{-j\epsilon'}}{\eta^{1+\epsilon}}$$

for any $\eta > 0$. A simple use of the Borel Cantelli lemma shows (24). □

3.3.2. *Proof of Theorem 2 for $p \in (p_\chi^-, p_\chi^+)$.* From (15)–(16) and the representation (12) for the partition function of a single cascade, we see that that $\mathcal{S}_{\tilde{\mu}}(j,p)$ exactly has the same structure as the quantity $\mathcal{N}_j(p)$ of section 3.3.1 where $Z^{(m,r)} = \overline{\mu}_\infty^{(m,r)}([0,T])^p$ are random variables distributed as $Z = \mu_\infty([0,T])^p$.

By definition (recall (17)–(18)), the condition $-p\tau'(p) + \tau(p) < \chi$ holds for any $p \in (p_\chi^-, p_\chi^+)$, and by Remark 1, $\mathbb{E}\left[|Z|^{1+\epsilon}\right] < \infty$ for ϵ small enough.

Thus, an application of Proposition 1 yields the almost sure convergence:

$$2^{j\tau_\chi(p)}\mathcal{S}_{\tilde{\mu}}(j,p) = 2^{j(\tau(p)-\chi)}\mathcal{S}_{\tilde{\mu}}(j,p) \xrightarrow{j\to\infty} \mathbb{E}\left[\mu_\infty([0,T])^p\right]. \tag{26}$$

This proves the theorem 2 for the case $p \in (p_\chi^-, p_\chi^+)$.

3.3.3. *Proof of Theorem 2 for $p \notin (p_\chi^-, p_\chi^+)$.* The following proof is an adaptation of the corresponding proof in [23]. We need the following notations:

$$\begin{aligned}
\mathcal{S}_{\tilde{\mu}}{}^*(j) &= \sup_{k\in[0,N-1]} \tilde{\mu}_\infty([k2^{-j}T,(k+1)2^{-j}T]),\\
m_{sup}(p) &= \limsup_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu}}(j,p)}{-j}, \quad m_{inf}(p) = \liminf_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu}}(j,p)}{-j},\\
m_{sup}^* &= \limsup_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu}}(j)^*}{-j}, \quad m_{inf}^* = \liminf_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu}}(j)^*}{-j}.
\end{aligned}$$

In Section 3.3.2 we proved that for all $p \in (p_\chi^-, p_\chi^+)$ the following holds almost surely:

$$m_{sup}(p) = m_{inf}(p) = \tau_\chi(p).$$

We may assume that on a event of probability one, this equality holds for all p in a countable and dense subset of (p_χ^-, p_χ^+).

From the sub-additivity of $x \mapsto x^\rho$,

$$\forall \rho \in]0,1[,\ \forall p \in \mathbb{R} \quad \mathcal{S}_{\tilde{\mu}}(p,j)^\rho \le \mathcal{S}_{\tilde{\mu}}(\rho p, j),$$

and thus

$$m_{inf}(p) \ge \frac{m_{inf}(\rho p)}{\rho}.$$

But we have seen that $m_{inf}(\rho p) = \tau_\chi(\rho p)$, for a dense subset of $\rho p \in (p_\chi^-, p_\chi^+)$. Assume now for simplicity that $p \ge p_\chi^+$ and let $\rho \to (p_\chi^+/p)$, we get

$$\forall p \ge p_\chi^+, \quad \frac{m_{inf}(p)}{p} \ge \frac{\tau_\chi(p_\chi^+)}{p_\chi^+} = \frac{\tau(p_\chi^+) - \chi}{p_\chi^+} = h_\chi^+, \tag{27}$$

where we have used (17)

On the other hand, let $p > 0$, $q \in [0, p_\chi^+)$, and $q' \in [0, q)$, we have

$$\begin{aligned} \mathcal{S}_{\tilde{\mu}}(j,q) &= \sum_{k=0}^{N-1} \tilde{\mu}_\infty([k2^{-j}T,(k+1)2^{-j}T])^q \\ &\leq \mathcal{S}_{\tilde{\mu}}{}^*(j)^{q-q'} \mathcal{S}_{\tilde{\mu}}(j,q') \\ &\leq \mathcal{S}_{\tilde{\mu}}(j,p)^{\frac{q-q'}{p}} \mathcal{S}_{\tilde{\mu}}(j,q'). \end{aligned}$$

Thus

$$m_{sup}(q) \geq (q-q') \frac{m_{sup}(p)}{p} + m_{inf}(q'),$$

then

$$\frac{m_{sup}(p)}{p} \leq \frac{m_{sup}(q) - m_{inf}(q')}{q-q'} = \frac{\tau_\chi(q) - \tau_\chi(q')}{q-q'}.$$

Taking the limit $q' \to q^-$

$$\frac{m_{sup}(p)}{p} \leq \inf_{q \in [0, p_\chi^+)} \tau'_\chi(q) \leq \tau'_\chi(p_\chi) = h_\chi^+.$$

Merging this last relation with (27) leads to

$$\forall p \geq p_\chi^+, \quad h_\chi^+ \leq \frac{m_{inf}(p)}{p} \leq \frac{m_{sup}(p)}{p} \leq h_\chi^+, \tag{28}$$

which proves Theorem 2 for $p \in [p_\chi^+, +\infty[$. The proof for $p \leq p_\chi^-$ is similar.

3.3.4. *Proof of Theorem 3.* The following proof is an adaptation of the corresponding proof in [23]. We have for $p > 0$,

$$\mathcal{S}_{\tilde{\mu}}{}^*(j)^p \leq \mathcal{S}_{\tilde{\mu}}(j,p) \leq N \mathcal{S}_{\tilde{\mu}} * (j)^p = \lfloor 2^{j\chi} \rfloor 2^j \mathcal{S}_{\tilde{\mu}}{}^*(j)^p,$$

thus

$$p m^*_{inf,sup} \geq m_{inf,sup}(p) \geq 1 + \chi + p m^*_{inf,sup},$$

which means that

$$\frac{m_{inf,sup}(p)}{p} - \frac{1+\chi}{p} \geq m^*_{inf,sup} \geq \frac{m_{inf,sup}(p)}{p},$$

and taking the limit $p \to +\infty$ and using (28) proves that

$$m^*_{sup} = m^*_{inf} = h_\chi^+,$$

which proves (20). The proof of (21) is obtained analogously by considering $p < 0$.

3.4. *Multifractal formalism and "negative dimensions".* Let $D(h)$ be the Legendre transform of $\tau(p)$:

$$D(h) = \min_p (ph - \tau(p)),$$

The *multifractal formalism* [7] gives an interesting interpretation of $D(h)$, as soon as $D(h) > 0$, in terms of dimension of set of points with the same regularity. For $\mathcal{M}$-cascades, this formalism holds [18], i.e., $D(h)$ corresponds to the Hausdorff dimension of the points $t \in [0, T]$ around which μ_∞ scales with the exponent h :

$$D(h) = dim_H \left\{ t,\ \limsup_{\epsilon \to 0} \frac{\log_2 \mu_\infty([t-\epsilon, t+\epsilon])}{\log_2(\epsilon)} = h \right\}. \tag{29}$$

The r.h.s. of (29) is usually referred to as the *singularity spectrum* and therefore the multifractal formalism simply states that $D(h)$ can be identified with the singularity spectrum of the cascade.

In a mixed asymptotic framework, our next result shows that some kind of multifractal formalism still holds for $D(h) < 0$ in the sense that $D(h)$ governs the behavior of the population histogram *per sample* of measure values at scale 2^{-j} as estimated over $2^{j\chi}$ cascade samples. In other words, $D(h)$ coincides with a box-counting dimension (sometimes referred to as a box dimension [10] or a coarse-grain spectrum [24]). Hence the Legendre transform of $\tau(p)$ can be interpreted as a "population" dimension even for singularity values above and below h_0^+ and h_0^-. Since for these values, one has $D(h) < 0$ they have been called "negative dimensions" by Mandelbrot [16]. This simply means that they cannot be observed on a single cascade sample but one needs at least $2^{j\chi}$ realizations to observe them with a "cardinality" like $2^{j(\chi + D(h))}$. In that respect, they have also been referred to as "latent" singularities [17].

Theorem 4. *Assume $p_\chi^+ < \infty$, $p_\chi^- > -\infty$ and $\tau(p_\chi^+) > 0$. Let $h \in (h_\chi^+, h_\chi^-)$, then:*

$$\lim_{\varepsilon \to 0} \underline{\lim}_{j} \frac{1}{j} \log \# \left\{ k \in \{0, \ldots, N-1\} \mid 2^{-j(h+\varepsilon)} \le \tilde{\mu}(I_{j,k}) \le 2^{-j(h-\varepsilon)} \right\} = \chi + D(h), \tag{30}$$

$$\lim_{\varepsilon \to 0} \overline{\lim}_{j} \frac{1}{j} \log \# \left\{ k \in \{0, \ldots, N-1\} \mid 2^{-j(h+\varepsilon)} \le \tilde{\mu}(I_{j,k}) \le 2^{-j(h-\varepsilon)} \right\} = \chi + D(h). \tag{31}$$

Proof. $1^{\mathbf{st}}$ **step:** We focus on the cases that yield to negative dimensions, i.e. $h \in (h_\chi^+, h_0^+) \cup (h_0^-, h_\chi^+)$. For simplicity assume $h \in (h_\chi^+, h_0^+) = (\tau'(p_\chi^+), \tau'(p_0^+))$. We can write $h = \tau'(p)$ for some $p \in (p_0^+, p_\chi^+)$ and if we define

$$\chi' = \tau(p) - p\tau'(p) \in (0, \chi)$$

we easily get that $h = \tau'(p_{\chi'}^+)$ and $D(h) = -\chi'$. Thus the theorem amounts to assess the magnitude of

$$\#\left\{k \in \{0, \dots, N-1\} \mid 2^{-j(\tau'(p_{\chi'}^+)+\varepsilon)} \leq \tilde{\mu}(I_{j,k}) \leq 2^{-j(\tau'(p_{\chi'}^+)-\varepsilon)}\right\}$$

as $\simeq 2^{j(\chi-\chi')}$.

First we derive a lower bound for this cardinality. The idea is to split the data into blocks of size $2^j \left\lfloor 2^{j\chi'} \right\rfloor$ and rely on the behavior of the supremum of $\tilde{\mu}(I_{j,k})$ under mixed asymptotic with index χ'. More precisely let $N' = 2^j \left\lfloor 2^{j\chi'} \right\rfloor$ and define the blocks

$$\mathbb{B}_a = \{aN', \dots, (a+1)N' - 1\}, \qquad \text{for } a = 0, \dots, M-1 := \lfloor N/N' \rfloor - 1.$$

Fix $a \in \{0, \dots, M-1\}$, then for any $p_1 < p_2 < p_{\chi'}^+$ we have

$$\sup_{k \in \mathbb{B}_a} \tilde{\mu}(I_{j,k})^{p_2-p_1} \geq \frac{\sum_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k})^{p_2}}{\sum_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k})^{p_1}} := 2^{j(\tau_{\chi'}(p_1)-\tau_{\chi'}(p_2))} Q_j^{(a)}(p_1, p_2), \tag{32}$$

where

$$Q_j^{(a)}(p_1, p_2) = \frac{\sum_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k})^{p_2} 2^{j\tau_{\chi'}(p_2)}}{\sum_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k})^{p_1} 2^{j\tau_{\chi'}(p_1)}}.$$

Clearly the law of $Q_j^{(a)}(p_1, p_2)$ does not depend on a, and $Q_j^{(0)}(p_1, p_2)$ is the ratio of two rescaled partition functions in mixed asymptotic with index χ'. Hence by (26), $Q_j^{(0)}(p_1, p_2)$ converges almost surely to the non zero constant $\mathbb{E}\left[\mu_\infty([0,T])^{p_2}\right] / \mathbb{E}\left[\mu_\infty([0,T])^{p_1}\right]$. We deduce that for all fixed $a \leq M-1$, and $p_1, p_2 \in (0, p_{\chi'}^+)$, the sequence $(1/Q_j^{(a)}(p_1, p_2))_{j \geq 0}$ is bounded in probability. Write now, by (32), and $\tau_{\chi'}(p) = \tau(p) - \chi'$ for $p < p_{\chi'}^+$,

$$\sup_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k}) 2^{j(\tau'(p_{\chi'}^+)+\epsilon)} \geq Q_j^{(a)}(p_1, p_2) 2^{-j[\frac{\tau(p_2)-\tau(p_1)}{p_2-p_2} - \tau'(p_{\chi'}^+) - \epsilon]}$$

and choose p_1, p_2 fixed but close enough to $p_{\chi'}^+$. This yields, for all $j \geq 0$:

$$\sup_{k\in\mathbb{B}_a} \tilde{\mu}(I_{j,k}) 2^{j(\tau'(p_{\chi'}^+)+\epsilon)} \geq Q_j^{(a)}(p_1, p_2) 2^{j\epsilon/2}.$$

Then using that $1/Q_j^{(a)}(p_1,p_2)$ is bounded in probability, we get $\mathbb{P}(\sup_{k\in\mathbb{B}_a}\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\varepsilon)})\geq\mathbb{P}(1/Q_j^{(a)}(p_1,p_2)\leq 2^{j\epsilon/2})\geq 1/2$ for j large enough.

Remark now that the cardinality of the set $\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\varepsilon)}\}$ is immediately lower bounded by the sum

$$\sum_{a=0}^{M-1} 1_{\left\{\sup_{k\in\mathbb{B}_a}\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\varepsilon)}\right\}}$$

of i.i.d. Bernoulli variables with parameter greater than 1/2. Then it is easily deduced, using the Borel Cantelli lemma and $M\sim_{j\to\infty}2^{(\chi-\chi')j}$ that with probability one:

$$\underline{\lim}_j\, 2^{-(\chi-\chi')j}\#\left\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\varepsilon)}\right\}\geq 1/4. \tag{33}$$

We now focus on upper bounds for the cardinality of the set

$$\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\eta)}\}$$

where η is some real number in a neighborhood of zero. It is simply derived from the connection with the partition function that for any $p>0$ this cardinality is lower than $\mathcal{S}_{\tilde{\mu}}(j,p)2^{j(\tau'(p^+_{\chi'})+\eta)p}$. Applying this with $p=p^+_{\chi'}$ and since, by (17), $\tau_\chi(p^+_{\chi'})=\tau(p^+_{\chi'})-\chi=p\tau'(p^+_{\chi'})+\chi'-\chi$ we get the following upper bound,

$$\begin{aligned}\#\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})+\eta)}\}&\\ \leq \mathcal{S}_{\tilde{\mu}}(j,p^+_{\chi'})2^{j\tau_\chi(p^+_{\chi'})}2^{j(\chi-\chi'+\eta p^+_{\chi'})}&.\end{aligned} \tag{34}$$

By $p^+_{\chi'}<p^+_\chi$, the convergence result (26) with $p=p^+_{\chi'}$ applies and we deduce for $\eta=-\epsilon<0$ that:

$$\overline{\lim_j}\, 2^{-(\chi-\chi')j}\#\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\geq 2^{-j(\tau'(p^+_{\chi'})-\varepsilon)}\}=0. \tag{35}$$

Then (30) is a consequence of (33) and (35).

Finally, the upper bound (31) is directly obtained by applying (34) with $\eta=\varepsilon$.

2nd step: We now deal with the more classical case $h\in[h_0^+,h_0^-]$. It is known, from the multifractal formalism for a single M-cascade on $[0,T]$ (see

[3, 24]), that with probability 1:

$$\lim_{\varepsilon\to 0}\underline{\lim}_{j}\frac{1}{j}\log\#\left\{k\in\{0,\dots,2^j-1\}\mid\tilde{\mu}(I_{j,k})\in[2^{-j(h+\varepsilon)},2^{-j(h-\varepsilon)}]\right\} = D(h). \tag{36}$$

For $m\in\{0,\dots,N_T-1\}$, and $\varepsilon>0$, $\eta>0$, denote by $A_j^{(m)}(\eta,\varepsilon)$ the event:

$$\#\left\{k\in\{0,\dots,2^j-1\}\mid\tilde{\mu}(I_{j,2^jm+k})\in[2^{-j(h+\varepsilon)},2^{-j(h-\varepsilon)}]\right\}\geq 2^{j(D(h)-\eta)}.$$

Using the independence of the $\mathcal{M}$-cascades $(\mu^{(m)})_m$, these events are independent and $\mathbb{P}(A_j^{(m)}(\eta,\varepsilon))$ does not depend on m. Moreover, by (36), for any $\eta>0$, there exists $\epsilon>0$ such that $\mathbb{P}(A_j^{(m)}(\eta,\varepsilon))\xrightarrow{j\to\infty}1$. We easily deduce that for any $\eta>0$ and ϵ small enough:

$$\underline{\lim}_{j}\frac{1}{N_T}\sum_{m=0}^{N_T-1}1_{\{A_j^{(m)}(\eta,\varepsilon)\}}\geq 1/2,\quad\text{almost surely.}$$

Since the cardinality of $\left\{k\in\{0,\dots,N-1\}\mid\tilde{\mu}(I_{j,k})\in[2^{-j(h+\varepsilon)},2^{-j(h-\varepsilon)}]\right\}$ is greater than $2^{j(D(h)-\eta)}\sum_{m=0}^{N_T-1}1_{\{A_j^{(m)}(\eta,\varepsilon)\}}$ we deduce that the left hand side of (30) is greater than $D(h)+\chi-\eta$, for any $\eta>0$. To end the proof, it suffices to show that the left hand side of (31) is lower than $D(h)+\chi$. This is easily done, as in the end of the first step, by relying on the asymptotic behavior of the partition function. ☐

3.5. *Central Limit Theorems.* In this section, we briefly study the rate of the convergence of $\mathcal{S}_{\tilde{\mu}}(j,p)$ as $j\to\infty$ of (19) in Theorem 2. Using the same notations as in the proof of Theorem 2, we write:

$$\mathcal{S}_{\tilde{\mu}}(j,p)=\left\lfloor 2^{j\chi}\right\rfloor 2^{-j\tau(p)}\mathbb{E}\left[\mu_\infty([0,T])^p\right]+A_j+B_j \tag{37}$$

where

$$A_j=\sum_{m=0}^{N_T-1}2^{-jp}\sum_{r\in\{0,1\}^j}\left(\prod_{i=1}^{j}W_{r|i}^{(m)p}\right)\left(\bar{\mu}_\infty^{(m,r)}([0,T])^p-\mathbb{E}\left[\mu_\infty([0,T])^p\right]\right)$$

and

$$B_j=\sum_{m=0}^{N_T-1}(2^{-jp}\sum_{r\in\{0,1\}^j}\prod_{i=1}^{j}W_{r|i}^{(m)p}-2^{-j\tau(p)})\mathbb{E}\left[\mu_\infty([0,T])^p\right].$$

Proposition 2. *Assume* (5)–(6) *and that, either* $p_\chi^+ = \infty$*, or* $p_\chi^+ < \infty$ *with* $\tau(p_\chi^+) > 0$*. If* $p_\chi^-/2 < p < p_\chi^+/2$ *then,*

$$2^{j(\tau(2p)-\chi)/2} A_j \xrightarrow{j\to\infty} \mathcal{N}(0,\, \mathit{Var}\,(\mu_\infty([0,T])^p)\,).$$

Proof. Consistently with the notations of Section 3.3.1, we define, for every $r \in \{0,1\}^j$ and $m = 0, \dots, N_T - 1$, the random variables $\tilde{Z}^{(m,r)} = \bar{\mu}_\infty^{(m,r)}([0,T])^p - \mathbb{E}\,[\mu_\infty([0,T])^p]$ and denote by $\tilde{Z} = \mu_\infty([0,T])^p - \mathbb{E}\,[\mu_\infty([0,T])^p]$ their common law. Furthermore, we will need the quantity

$$\eta_{m,r,j}(p) = 2^{j(\tau(2p)-\chi)/2} 2^{-jp} \left(\prod_{i=1}^{j} W_{r|i}^{(m)p} \right) \tilde{Z}^{(m,r)}, \tag{38}$$

and the following family of σ-fields: for $j \geq 0$

$$\mathcal{F}_{-1,j} := \sigma\big(W_r^{(m)},\ |r| \leq j,\ m = 0, \dots, N_T - 1\big)$$

and for every $k = 0, \dots, n(j) = 2^j(N_T - 1)$

$$\mathcal{F}_{k,j} = \mathcal{F}_{-1,j} \vee \sigma\big(\tilde{Z}^{(m,r)},\ \bar{r} + 2^j m \leq k\big).$$

For fixed j, we have a one-to-one correspondence between (m,r) and $k = \bar{r} + 2^j m$, so abusing notation slightly, we write $\eta_{k,j}(p)$ instead of $\eta_{m,r,j}(p)$ in (38) when no confusion is possible. With these notations,

$$2^{(\tau(2p)-\chi)/2} A_j = \sum_{k=0}^{n(j)} \eta_{k,j}(p)$$

where $\eta_{k,j}(p)$ is $\mathcal{F}_{k,j}$-measurable and

$$\mathbb{E}\,[\eta_{k,j}(p) \,|\, \mathcal{F}_{k-1,j}] = 0, \quad \forall k = 0, \dots, n(j).$$

Thus, we are dealing with a triangular array of martingale increments. Let us consider the sum of the conditional variances:

$$V_j = \sum_{k=0}^{n(j)} \mathbb{E}\left[\eta_{k,j}(p)^2 \,|\, \mathcal{F}_{k-1,j}\right]. \tag{39}$$

We have

$$V_j = \mathrm{Var}(\tilde{Z}) 2^{j(\tau(2p)-\chi)} 2^{-2jp} \sum_{m=0}^{N_T-1} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} \left(W_{r|i}^{(m)}\right)^{2p},$$

thus by application of Proposition 1 (with the choice of $Z^{(m,r)}$ equal to 1) we get,

$$V_j \xrightarrow{j\to\infty} \mathrm{Var}(\tilde{Z}).$$

Hence the proposition will be proved, if we can show that the triangular array satisfies a Lindeberg condition: for some $\epsilon > 0$,

$$V_j^{(\epsilon)} = \sum_{k=0}^{n(j)} \mathbb{E}\left[|\eta_{k,j}(p)|^{2+\epsilon} \mid \mathcal{F}_{k-1,j}\right] \xrightarrow{j\to\infty} 0.$$

But, we have

$$V_j^{(\epsilon)} = \mathbb{E}\left[|W|^{2+\epsilon}\right] 2^{j(\tau(2p)-\chi)(1+\epsilon/2)} 2^{-j(2+\epsilon)p} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} \left(W_{r|i}^{(m)}\right)^{2+\epsilon}$$

and by application of the Proposition 1, the order of magnitude of $V_j^{(\epsilon)}$ is $2^{j\left((\tau(2p)-\chi)(1+\epsilon/2)-(\tau((2+p)\epsilon)-\chi)\right)}$. Thus, it can be seen that $V_j^{(\epsilon)}$ converges to zero, for ϵ small enough, by the condition $2p\tau'(2p) - \tau(2p) > -\chi$. This ends the proof of the proposition. ☐

PROPOSITION 3. *Assume* (5)–(6) *and that, either* $p_\chi^+ = \infty$, *or* $p_\chi^+ < \infty$ *with* $\tau(p_\chi^+) > 0$. *Then:*

1. *If* $\tau(2p) - 2\tau(p) > 0$ *we have,*

$$2^{j(\tau(p)-\chi/2)} B_j \to \mathcal{N}\big(0, c(p)\big), \tag{40}$$

   where $c(p) > 0$ *depends on the law of* W *and* p.
2. *If* $\tau(2p) - 2\tau(p) = 0$, *we have* $Var(B_j) = O(j2^{-j(\tau(2p)-\chi)})$.
3. *If* $\tau(2p) - 2\tau(p) < 0$, *we have* $Var(B_j) = O(2^{-j(\tau(2p)-\chi)})$.

PROOF. Denote $\nu_j^{(m)}$ the measures defined at the step j of the construction of the M-cascade on $[0,1]$ based on $W^p/\mathbb{E}\left[W^p\right]$:

$$\nu_j^{(m)}([0,1]) = 2^{-j} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} (W_{r|i}^{(m,r)})^p \mathbb{E}\left[W^p\right]^{-j}, \qquad \text{for } m \in \{0,\dots,N_T-1\}.$$

With this notation we have,

$$B_j = \mathbb{E}\left[\mu_\infty([0,T])^p\right] 2^{-j\tau(p)} \sum_{m=0}^{N_T-1} \left(\nu_j^{(m)}([0,1]) - 1\right) \tag{41}$$

and using Kahane and Peyrière results [11], we know that for each m the sequence $(\nu_j^{(m)}([0,1]))_j$ is bounded in $\mathbf{L}^q$ as soon as $\tau(pq) - q\tau(p) > 0$.

We first focus on the case $\tau(2p) - 2\tau(p) > 0$. Hence the sequence $(\nu_j^{(m)}([0,1]))_j$ is bounded in $\mathbf{L}^{2+\epsilon}$-norm for some $\epsilon > 0$. Using that $(\nu_j^{(m)}([0,1]) - 1)_m$ is a centered i.i.d. sequence and classical considerations for triangular array of martingale increments, one can show that a central limit theorem holds:

$$N_T^{-1/2} \sum_{m=0}^{N_T - 1} (\nu_j^{(m)}([0,T]) - 1) \xrightarrow{j\to\infty} \mathcal{N}(0, \mathrm{Var}(\nu_\infty^{(0)}([0,1]))),$$

where $\nu_\infty^{(0)}([0,1]) = \lim_{j\to\infty} \nu_j^{(0)}([0,1])$. From this and (41) we deduce (40) with $c(p) = \mathbb{E}\left[\mu_\infty([0,T])^p\right]^2 \mathrm{Var}(\nu_\infty^{(0)}([0,1]))$.

In the cases $\tau(2p) - 2\tau(p) \le 0$, by (41) again we have

$$\mathrm{Var}(B_j) = \left\lfloor 2^{j\chi} \right\rfloor 2^{-j2\tau(p)} \mathbb{E}\left[\mu_\infty([0,T])^p\right]^2 \mathrm{Var}(\nu_j^{(0)}([0,1])).$$

Now $\mathrm{Var}(\nu_j^{(0)}([0,1])) = \mathbb{E}\left[\nu_j^{(0)}([0,1])^2\right] - 1$ is unbounded as $j \to \infty$, but a careful look at the computations in Lemma 2 with $\epsilon = 1$ yields to

$$\mathbb{E}\left[\nu_j^{(0)}([0,1])^2\right] \sim_{j\to\infty} \sum_{l=0}^{j} 2^{-l} 2^{l(2\tau(p)-\tau(2p))}.$$

We deduce that $\mathrm{Var}(B_j) = O\big(2^{-j(2\tau(p)-\chi)} \sum_{l=0}^{j} 2^{-l} 2^{l(2\tau(p)-\tau(2p))}\big)$. Then, the theorem follows in the cases $\tau(2p) - 2\tau(p) = 0$ and $\tau(2p) - 2\tau(p) < 0$. ☐

REMARK 3. *By* (37) *the difference between* $2^{(\tau(p)-\chi)j}\mathcal{S}_{\tilde\mu}(j,p)$ *and its limit is decomposed into two dissimilar error terms: particularly the fact that the contribution of* B_j *converges to zero is due to the observation of a large number of integral scales, whereas the contribution of* A_j *vanishes as the sampling step tends to zero.*

In the case $\tau(2p) - 2\tau(p) > 0$, *the contribution of* B_j *strictly dominates and* $2^{-(\tau(p)-\chi)}\mathcal{S}_{\tilde\mu}(j,p) - \mathbb{E}\left[\mu_\infty([0,T])^p\right]$ *is of magnitude* $2^{-j\chi} \sim N_T^{-1/2}$.

If $\tau(2p) - 2\tau(p) < 0$, *the magnitude of* A_j *and* B_j *are the same and* $2^{-(\tau(p)-\chi)}\mathcal{S}_{\tilde\mu}(j,p) - \mathbb{E}\left[\mu_\infty([0,T])^p\right]$ *is asymptotically bounded by terms of magnitude* $2^{j/2(-\chi+2\tau(2p)-\tau(2p))}$. *This rate of convergence is slower than* $N_T^{-1/2}$.

4. Extension to wavelet based partition functions.

The behavior of the partition function provides an evaluation for the regularity of the sample path of the process $t \mapsto \tilde\mu([0,t])$. However, it is more natural to assess this regularity via the behavior of wavelet coefficients.

4.1. *Notations.* In this section we assume, for notational convenience, that $T = 1$. Consider now g a "generalized box" function. It is a real valued function that satisfies the following assumptions

(H1) g has compact support included in $[0, 2^J]$, for some $J \geq 0$.
(H2) g is piecewise continuous.
(H3) g is at least non zero on an interval.

Following the common wavelet notation, we define

$$g_{j,k}(t) = g(2^j t - k).$$

The support of $g_{j,k}(t)$ is

$$\text{Supp } g_{j,k} = [2^{-j}k, 2^{-j}k + 2^{J-j}]. \tag{42}$$

In the sequel, if μ is a random measure, for any Borel function f we will use the notation

$$\langle \mu, f \rangle = \int f(t) d\mu(t).$$

4.2. *The generalized partition function : scaling properties.* We define the generalized partition function of an M-cascade μ_∞ on $[0, 1]$ at scale 2^{-j} as

$$\mathcal{S}_{\mu,g}(j, p) = \sum_{k=0}^{2^j - 2^J - 1} |\langle \mu_\infty, g_{j,k} \rangle|^p. \tag{43}$$

Remark that for simplicity we removed a finite number of border terms, and that, in the case $g(t)$ is the "box" function $g(t) = 1_{[0,1]}(t)$ we recover the partition function of Section 2.1.

Let us study the scaling of $\mathbb{E}\left[\mathcal{S}_{\mu,g}(j, p)\right]$.

Proposition 4. *Assume* (5)–(6)*. Then, we have* $K_1 2^{-j\tau(p)} \leq \mathbb{E}\left[\mathcal{S}_{\mu,g}(j, p)\right] \leq K_2 2^{-j\tau(p)}$ *for* K_1, K_2, *two positive constants depending on* p, W *and* g.

Proof. Since $|g(t)|$ is clearly a bounded function, we have

$$\mathbb{E}\left[|\langle \mu_\infty, g_{j,k} \rangle|^p\right] \leq C \mathbb{E}\left[\mu_\infty([2^{-j}k, 2^{-j}k + 2^{J-j}])^p\right],$$

where C is a constant. We write $\mu_\infty([2^{-j}k, 2^{-j}k + 2^{J-j}]) = \sum_{l=0}^{2^J-1} \mu_\infty(I_{j,k+l})$, and deduce

$$\mathbb{E}\left[|\langle \mu_\infty, g_{j,k} \rangle|^p\right] \leq C \mathbb{E}\left[|\mu_\infty[0, 2^{-j}]|^p\right] = K 2^{-j(\tau(p)+1)}, \tag{44}$$

where K only depends on g and the law of W. By (43) we get the upper bound for $\mathbb{E}\left[\mathcal{S}_{\mu,g}(j,p)\right]$.

For the lower bound, let us write that $\mathcal{S}_{\mu,g}(j,p)$ is greater than

$$\sum_{k'=0}^{2^{j-J}-1} |\left\langle \mu_\infty, g_{j,2^J k'} \right\rangle|^p.$$

But $g_{j,2^J k'}$ is supported on $[k' 2^{J-j}, (k'+1)2^{J-j}]$, thus applying Lemma 3 in the Appendix B with $a = j - J$, we deduce:

$$\left\langle \mu_\infty, g_{j,2^J k'} \right\rangle = 2^{J-j} \left(\prod_{i=1}^{j-J} W_{r|i} \right) Z$$

where, in law, Z is equal to $\langle \mu_\infty, g_{J,0} \rangle$. Thus $\mathbb{E}\left[|\langle \mu_\infty, g_{j,k} \rangle|^p\right]$ is greater than

$$2^{p(J-j)} \mathbb{E}\left[W^p\right]^{j-J} \mathbb{E}\left[|\langle \mu_\infty, g_{J,0} \rangle|^p\right] = K 2^{-j(\tau(p)+1)} \mathbb{E}\left[|\langle \mu_\infty, g_{J,0} \rangle|^p\right].$$

Applying Lemma 4 with $f = g_{J,0}$ shows that $\mathbb{E}\left[|\langle \mu_\infty, g_{J,0} \rangle|^p\right]$ is some positive constant. Then the lower bound for $\mathbb{E}\left[\mathcal{S}_{\mu,g}(j,p)\right]$ easily follows. ☐

4.3. *The partition function in the mixed asymptotic framework.* Following (15), we define the partition function in the mixed asymptotic framework as

$$\mathcal{S}_{\tilde{\mu},g}(j,p) = \sum_{m=0}^{N_T-1} \mathcal{S}^{(m)}_{\mu,g}(j,p),$$

where $\mathcal{S}^{(m)}_{\mu,g}(j,p)$ is the partition function of $\mu^{(m)}_\infty$, i.e.,

$$\mathcal{S}^{(m)}_{\mu,g}(j,p) = \sum_{k=0}^{2^j-2^J-1} \left| \left\langle \mu^{(m)}_\infty, g_{j,k} \right\rangle \right|^p.$$

We have the following result.

THEOREM 5. **Scaling of the generalized partition function in a mixed asymptotic**
Let $p > 0$, then under the same assumptions as Theorem 2 the power law scaling of $\mathcal{S}_{\tilde{\mu},g}(j,p)$ is given by

$$\lim_{j\to\infty} \frac{\log_2 \mathcal{S}_{\tilde{\mu},g}(j,p)}{-j} \xrightarrow[a.s.]{} \tau_\chi(p).$$

PROOF. Using Proposition 4 we have, $\lim_{j\to\infty} \frac{1}{-j}\log_2 \mathbb{E}\left[\mathcal{S}_{\tilde{\mu},g}(j,p)\right] = \tau_\chi(p)$, and we just need to prove that almost surely,

$$\mathcal{S}_{\tilde{\mu},g}(j,p) - \mathbb{E}\left[\mathcal{S}_{\tilde{\mu},g}(j,p)\right] = o(2^{-j\tau_\chi(p)}).$$

Using lemma 5 and 6 of appendix B, this is done in the exact same way as the proof of (24) in Proposition 1. □

5. Link with Besov spaces. Following [9], one may define for a measure μ on $[0,T]$, the boundary of its Besov domain as the function $s_\mu : (0,\infty) \to \mathbb{R}\cup\{\infty\}$ given by

$$s_\mu(1/p) = \sup\left\{\sigma \in \mathbb{R} \mid \sup_{j\geq 0} 2^{j\sigma}\left(2^{-j}\sum_{k=0}^{2^j-1}|\mu(I_{j,k})|^p\right)^{1/p} < \infty\right\}.$$

The following proposition can be shown (see [9]).

PROPOSITION 5. *The function s_μ is an increasing, concave function, with a derivative bounded by* 1.

Let us stress that the condition $s'_\mu(1/p) \leq 1$ is a simple consequence of the Sobolev embedding for Besov spaces. The Theorem 1 characterizes the Besov domain for μ_∞ a M-cascade on $[0,T]$:

$$\forall p > 0, \quad s_{\mu_\infty}(1/p) = \begin{cases} \frac{\tau(p)+1}{p} & \text{if } \frac{1}{p} > \frac{1}{p_0} \\ h_0^+ + \frac{1}{p} & \text{if } \frac{1}{p} \leq \frac{1}{p_0} \end{cases}.$$

If we denote $s(\frac{1}{p}) = \frac{\tau(p)+1}{p}$ then, it is simply checked that the condition $1/p > 1/p_0^+$ is equivalent to $s'(1/p) < 1$. Hence Proposition 5 explains why for $1/p \leq 1/p_0^+$ the boundary of the Besov domain must be linear with a slope equal to one.

In mixed asymptotic the support of the measure grows with j but we can still define, using the notations of Section 3, the index:

$$s_{\tilde{\mu}}^\chi(1/p) = \sup\left\{\sigma \in \mathbb{R} \mid \sup_{j\geq 0} 2^{j\sigma}\left(N_T^{-1}2^{-j}\sum_{k=0}^{N_T 2^j-1}|\tilde{\mu}(I_{j,k})|^p\right)^{1/p} < \infty\right\}.$$

Then, it is simply checked that Theorem 2 implies $s_{\tilde{\mu}}^\chi(1/p) = s(1/p)$ when $s'(1/p) < 1+\chi$, and $s_{\tilde{\mu}}^\chi(1/p) = h_\chi^+ + \frac{1+\chi}{p}$ otherwise. This shows how the linear part in $s_{\tilde{\mu}}^\chi$ is shifted to larger values of p under the mixed asymptotic framework.

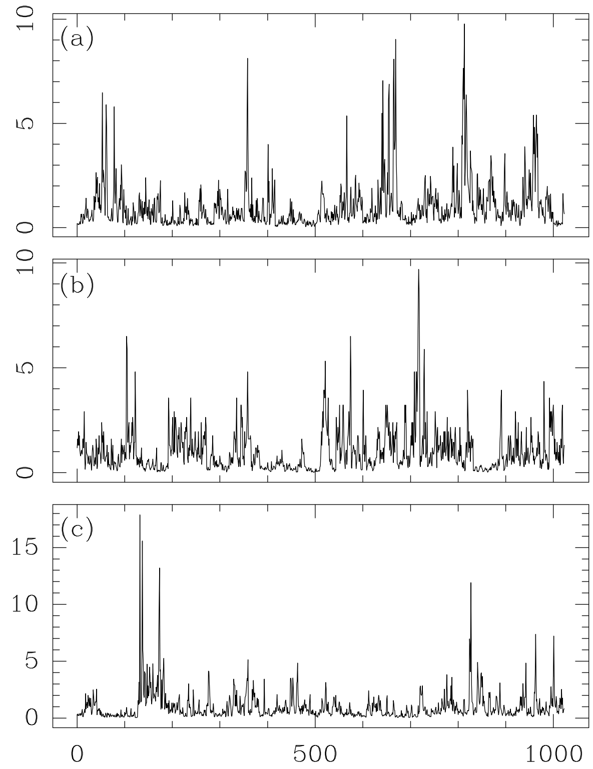

FIG 1. *Three synthetic samples of $\mathcal{M}$-cascades with $T = 2^{13}$ and $\lambda^2 = 0.2$: (a) log-Normal sample, (b) log-Poisson sample with $\delta = -0.1$ and (c) log-Gamma sample with $\beta = 10$. In fact we used $\mu_{j_{\max}+5}[n, n+1]_{n=0\ldots L}$ as a proxy of $\mu_\infty[n, n+1]$ with $j_{\max} = \log_2(T) = 13$ (see Eq. (3) for the definition of μ_j).*

6. Numerical examples and applications. Our goal in this section is not to focus on statistical issues and notably on precise estimates of multifractal exponents from empirical data. We rather aim at illustrating the results of theorem 2 on precise examples, namely random cascades with respectively log-normal, log-Poisson and log-Gamma statistics. For the sake of simplicity we will consider exclusively scaling of partition function for $p \geq 0$[1]. In order to facilitate the comparison of the three models, λ^2 will represent the so-called intermittency coefficient, i.e.,

$$\lambda^2 = -\tau''(0)$$

where $\tau(p)$ is defined in Eq. (7). This value will be fixed for the three considered models. Let $\{W_r\}$ be the cascade random generators as defined in Eq. (3) and let $\omega_r = \ln W_r$.

In the simplest, log-Normal case the $\{\omega_r\}_r$ are normally distributed random variables of variance $\lambda^2 \ln(2)$. Thanks to the condition $\mathbb{E}\left[W_r\right] = \mathbb{E}\left[e^{\omega_r}\right] = 1$, their mean is necessarily $-\lambda^2 \ln(2)/2$. In that case, the cumulant generating function $\tau(p)$ defined in Eq. (7) is simply a parabola:

$$\tau^n(p) = p(1+\frac{\lambda^2}{2}) - \frac{\lambda^2}{2}p^2 - 1$$

In the log-Poisson case, the variables ω_r are written as $\omega_r = m_0 \ln(2) + \delta n_r$ where the n_r are integers distributed according to a Poisson law of mean $\gamma \ln(2)$. It results that $\tau(p) = p(1-m_0) + \gamma(1-e^{p\delta}) - 1$. If one sets $\tau(1) = 0$ and $\tau''(0) = -\lambda^2$, one finally gets the expression of $\tau(p)$ of a log-Poisson cascade with intermittency coefficient λ^2:

$$\tau^p(p) = p\left(1 + \frac{\lambda^2}{\delta^2}(e^\delta - 1)\right) + \frac{\lambda^2}{\delta^2}(1 - e^{p\delta}) \tag{45}$$

In third case the variables ω_r are drawn from a Gamma distribution. If x is a random variable of pdf $\beta^{\alpha \ln(2)} x^{\alpha \ln(2)-1} e^{-\beta x}/\Gamma(\alpha \ln(2))$, then one chooses $\omega_r = x + m_0 \ln(2)$ and it is easy to show that $\tau(p)$ is defined only for $p < \beta$ and in this case $\tau(p) = p(1-m_0) + \alpha(1 - p/\beta)$. By fixing $\tau(1) = 1$ and $\tau''(0) = \lambda^2$, on obtains:

$$\tau^g(p) = p\left(1 - \lambda^2\beta^2 \ln\frac{\beta-1}{\beta}\right) + \lambda^2\beta^2 \ln\frac{\beta-p}{\beta} \tag{46}$$

Notice that one recovers the log-normal case from both log-Poisson and log-Gamma statistics in the limits $\delta \to 0$ and $\beta \to +\infty$ respectively.

---

[1] Numerical methods for estimating $\tau(p)$ for $p < 0$ are trickier to handle

For the 3 cases, one can explicitely compute all the mixed asymptotic exponents as functions of χ: In particular the values of $p_\chi^\pm$ read:

$$\begin{aligned}
p_{\chi,n}^\pm &= \pm\sqrt{\frac{2(1+\chi)}{\lambda^2}} \\
p_{\chi,p}^\pm &= \frac{W\left(\pm, \frac{\delta^2(1+\chi)-\lambda^2}{e\lambda^2}\right)+1}{\delta} = p_{\chi,n}^\pm + \frac{2(1+\chi)}{3\lambda^2}\delta + \mathcal{O}(\delta^2) \\
p_{\chi,g}^\pm &= \beta\left[1+\frac{1+\chi}{\lambda 2\beta^2} - e^{1+W(\pm,-e^{-1-\frac{1+\chi}{\lambda^2\beta^2}})}\right] = p_{\chi,n}^\pm - \frac{4(1+\chi)}{3\lambda^2\beta} + \mathcal{O}(\beta^{-2})
\end{aligned}$$

where suffixes n, p, g stand for respectively log-normal, log-Poisson and log-Gamma cascades and $W(\pm, z)$ represent the two branches of the Lambert $W(z)$ function, solution of $W(z)e^{W(z)} = z$ that take (respectively positive and negative) real values for the considered arguments. For log-Poisson and log-Gamma cases, we have also indicated the asymptotic behavior in the limits $\delta \to 0$ and $\beta \to \infty$. The values $h_\chi^\pm$ can be easily deduced form their definition: $h_\chi^\pm = \tau'(p_\chi^\pm)$.

In Fig. 1 is plotted a sample of each of the three examples of $\mathcal{M}$-cascades. We chose $T = 2^{13}$ and $\lambda^2 = 0.2$ for all models while, in the log-Poisson case we have set $\delta = -0.1$ and $\beta = 10$ in the log-Gamma model. In each case, an approximation of the $\mathcal{M}$-cascade sample is generated. We chose to generate μ_{18} (as defined by Eq. (3)) so that the smallest scale involved is $l_{min} = 2^{-18}T = 2^{-5}$ (we have checked that the results reported below do not depend on l_{min}). An approximation of $\tilde{\mu}$ is generated by concatenating i.i.d. realizations of μ_{18}. Then, for each model and for each chosen value of χ, $\tau_\chi(p)$ ($p = 0 \ldots 6$) was obtained from a least square fit of the curve $\log_2 S_{\tilde{\mu}}(j, p)$ versus j over the range $j = 0 \ldots 6$. Let us recall that, for each value of j, the mixed asymptotic regime corresponds to sampling $\tilde{\mu}$ at scale $l = 2^{-j}T$ and over an interval of size $L = 2^{j\chi}T$. The exponents reported in figs. 2 and 3 represent the mean values of exponents estimated in that way using $N = 130$ experiments.

The log-Normal mixed asymptotic scaling exponents for $\chi = 0, 0.5, 1$ are represented in Fig. 2. For illustration purpose we have plotted $\tau_\chi(p) + \chi$ as a function of p: one clearly observes that, as the value of χ increases, the value of p_χ^+ below which the function is linear, also increases while the value of the slope h_χ^+ decreases. As expected, when χ increases $\tau_\chi(p) + \chi$ matches $\tau(p)$ over an increasing range of p values. Notice that the estimated exponents are very close the analytical predictions as represented by the dashed lines. Error bars on the mean value estimates are simply computed from the estimated r.m.s. over the 130 trials and are reported only for the

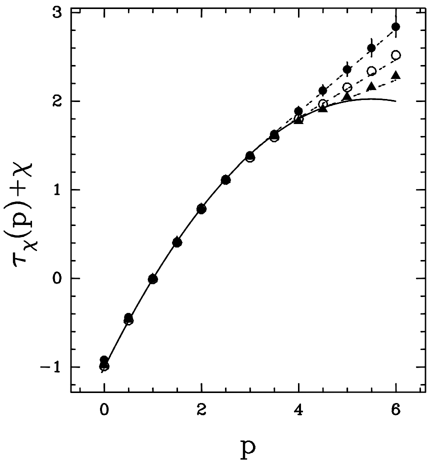

Fig 2. *Estimates of the function $\tau_\chi(p)$ of log-normal cascades with $\lambda^2 = 0.2$ for $\chi = 0$ (●) $\chi = 0.5$ (○) and $\chi = 1$ (▲). Dashed lines represent the corresponding analytical expression from theorem 2 and the solid line represents the function $\tau(q)$ as defined in Eq.* (7). *τ_χ is estimated from the average over 130 trials of $2^{j\chi}$ cascades samples. Error bars are reported on the $\chi = 0$ curve as vertical solid bar. These errors are of order of symbol size.*

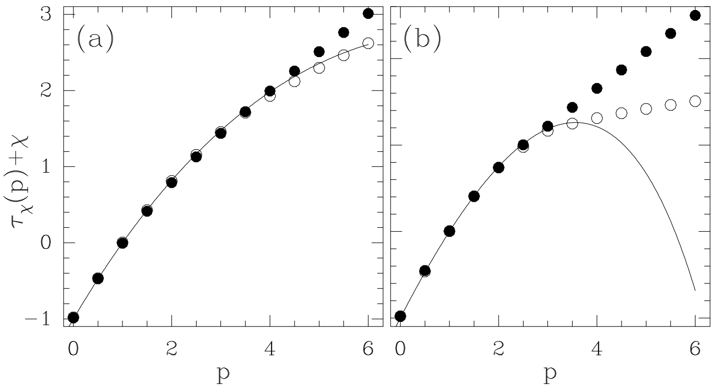

Fig 3. *Estimates of the function $\tau_\chi(p)$ of log-Poisson for $\chi = 0$ (●) and $\chi = 1$ (○). In both models we chose $T = 2^{13}$ and $\lambda^2 = 0.2$. (a) Log-Poisson case with $\delta = -0.1$. (b) Log-Gamma case with $\beta = 10$. Solid lines represent the curves $\tau(p)$.*

$\chi = 0$ curve. We can see that these errors are smaller or close to the symbol tickness.

In Fig. 3 are reported estimates of $\tau_\chi(p)$, $\chi = 0, 1$ for log-Poisson (fig. 3(a)) and log-Gamma (fig. 3(b)) samples. The solide lines represent the theoretical $\tau(p)$ functions for both models as provided by Eqs. (45) and (46). We used the same estimation procedure as for the log-normal case. One sees that, in both cases, since the intermittency coefficient is the same for the three models, the classical $\tau_0(p)$ curves are very similar to the log-normal curve (Fig. 2). However, these models behave very differently in mixed regime: for $\chi = 1$, log-Poisson and log-Gamma both estimated scaling exponents become closer to the respective values of $\tau(p)$ and are very easy to distinguish. Let us mention that such a analysis has been recently performed by two of us in order to distinguish two popular log-normal and log-Poisson models for spatial fluctuations of energy dissipation in fully developed turbulence [19].

APPENDIX A: LEMMA USED FOR THE PROOF OF THEOREM ??

LEMMA 1. *We have*

$$L_N^{1+\epsilon} \leq C 2^{j\chi} \mathbb{E}\left[\left|\mathcal{M}_j^{(0)}(p)\right|^{1+\epsilon}\right]$$

where $L_N^{1+\epsilon}$ *is defined by* (25) *and* C *is a constant that depends only on* ϵ.

PROOF. According to [25], if $\epsilon \in [0, 1]$ and if $\{X_i\}_{1 \leq i \leq P}$ are centered independent random variables one has

$$\mathbb{E}\left[\left|\sum_{i=1}^{P} X_i\right|^{1+\epsilon}\right] \leq C \sum_{i=1}^{P} \mathbb{E}\left[|X_i|^{1+\epsilon}\right],$$

where C is a constant that depends only on ϵ (and neither on the law of X nor on P). Applying it with $P = N_T = \lfloor 2^{j\chi} \rfloor$ to the expression (23) of $\mathcal{N}_j(p)$, and using the fact that the random variables $\{\mathcal{M}_j^{(m)}(p)\}_m$ defined by (22) are i.i.d, one gets

$$\begin{aligned} L_N^{1+\epsilon} &\leq C 2^{j\chi} \mathbb{E}\left[\left|\mathcal{M}_j^{(0)}(p) - \mathbb{E}\left[\mathcal{M}_j^{(0)}(p)\right]\right|^{1+\epsilon}\right] \\ &\leq C 2^{j\chi} \left(\mathbb{E}\left[\left|\mathcal{M}_j^{(0)}(p)\right|^{1+\epsilon}\right] + \mathbb{E}\left[\left|\mathcal{M}_j^{(0)}(p)\right|\right]^{1+\epsilon}\right). \end{aligned}$$

Using the Jensen inequality we get the result. □

Lemma 2. *Assume that* $\mathbb{E}\left[|Z|^{1+\epsilon}\right] < \infty$*. Then we have for all* m*,*

$$\mathbb{E}\left[\left|\mathcal{M}_j^{(m)}(p)\right|^{1+\epsilon}\right] \leq C 2^{-j(1+\epsilon)\tau(p)} \sum_{k=0}^{j} 2^{-k\tau(p(1+\epsilon))} 2^{k(1+\epsilon)\tau(p)},$$

where C *is a constant that depends only on* p *and* ϵ*.*

Proof. The proof of this result is very much inspired from [23]. Since the law of $\mathcal{M}_j^{(m)}(p)$ is independent of m, we forget the supscript m throughout the proof. Using the definition (22), one gets

$$\mathbb{E}\left[|\mathcal{M}_j(p)|^{1+\epsilon}\right] = 2^{-jp(1+\epsilon)} \mathbb{E}\left[\left|\sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} W_{r|i}^{p} Z^{(r)}\right|^{1+\epsilon}\right]. \tag{47}$$

Let

$$X = 2^{-jp} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} W_{r|i}^{p} Z^{(r)}, \tag{48}$$

then

$$X^2 = 2^{-2jp} \sum_{r_1\in\{0,1\}^j} \sum_{r_2\in\{0,1\}^j} \prod_{i=1}^{j} W_{r_1|i}^{p} W_{r_2|i}^{p} Z^{(r_1)} Z^{(r_2)}.$$

It can be rewritten as

$$X^2 = Y + D, \tag{49}$$

where Y corresponds to the non diagonal terms :

$$Y = 2^{-2jp} \sum_{r_1\in\{0,1\}^j} \sum_{\substack{r_2\in\{0,1\}^j \\ r_2\neq r_1}} \prod_{i=1}^{j} W_{r_1|i}^{p} W_{r_2|i}^{p} Z^{(r_1)} Z^{(r_2)}, \tag{50}$$

and D to the diagonal terms

$$D = 2^{-2jp} \sum_{r\in\{0,1\}^j} \prod_{i=1}^{j} W_{r|i}^{2p} \left(Z^{(r)}\right)^2. \tag{51}$$

The left hand side of (47) is nothing but $\mathbb{E}\left[|X|^{1+\epsilon}\right]$. By writing that $\mathbb{E}\left[|X|^{1+\epsilon}\right] = \mathbb{E}\left[(X^2)^{\frac{1+\epsilon}{2}}\right]$, using the sub-additivity of $x \mapsto x^{(1+\epsilon)/2}$, we get

$$\mathbb{E}\left[|X|^{1+\epsilon}\right] \leq \mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] + \mathbb{E}\left[D^{\frac{1+\epsilon}{2}}\right]. \tag{52}$$

Let us first work with the Y term. We factorize the common beginning of the words r_1 and r_2 in the expression (50) of Y

$$Y = 2^{-2jp} \sum_{k=0}^{j-1} \sum_{r\in\{0,1\}^k} \prod_{i=1}^{k} W_{r|i}^{2p} \sum_{\substack{r_1,r_2\in\{0,1\}^{j-k}\\ r_1|0\neq r_2|0}} \prod_{i=k+1}^{j} W_{rr_1|i}^{p} W_{rr_2|i}^{p} Z^{(r_1)} Z^{(r_2)}.$$

Again by the sub-additivity of $x \mapsto x^{(1+\epsilon)/2}$ and using the fact that the $W_{r|i}$ are i.i.d., one gets

$$\begin{aligned}\mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] \quad\leq\quad & 2^{-jp(1+\epsilon)} \sum_{k=0}^{j-1} \mathbb{E}\left[W^{p(1+\epsilon)}\right]^k \sum_{r\in\{0,1\}^k} \\ & \mathbb{E}\left[\Big(\sum_{\substack{r_1,r_2\in\{0,1\}^{j-k}\\ r_1|0\neq r_2|0}} \prod_{i=k+1}^{j} W_{rr_1|i}^{p} W_{rr_2|i}^{p} |Z^{(r_1)} Z^{(r_2)}|\Big)^{(1+\epsilon)/2}\right],\end{aligned}$$

and by using Jensen inequality

$$\begin{aligned}\mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] \quad\leq\quad & 2^{-jp(1+\epsilon)} \sum_{k=0}^{j-1} \mathbb{E}\left[W^{p(1+\epsilon)}\right]^k \sum_{r\in\{0,1\}^k} \\ & \Big(\sum_{\substack{r_1,r_2\in\{0,1\}^{j-k}\\ r_1|0\neq r_2|0}} \prod_{i=k+1}^{j} \mathbb{E}\left[W_{rr_1|i}^{p} W_{rr_2|i}^{p}\right] \mathbb{E}\left[|Z^{(r_1)} Z^{(r_2)}|\right] \Big)^{(1+\epsilon)/2}. \qquad (53)\end{aligned}$$

The variables $Z^{(r_1)}$ and $Z^{(r_2)}$ are independant with finite expectation, thus the term $\mathbb{E}\left[|Z^{(r_1)} Z^{(r_2)}|\right]$ is bounded by a constant C. Using $\prod_{i=k+1}^{j} \mathbb{E}\left[W_{rr_1|i}^{p} W_{rr_2|i}^{p}\right] = \mathbb{E}\left[W^p\right]^{2(j-k)}$, we deduce:

$$\begin{aligned}\mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] \quad\leq\quad & C2^{-jp(1+\epsilon)} \sum_{k=0}^{j-1} \mathbb{E}\left[W^{p(1+\epsilon)}\right]^k \mathbb{E}\left[W^p\right]^{(j-k)(1+\epsilon)} \\ & \sum_{r\in\{0,1\}^k} | \sum_{\substack{r_1,r_2\in\{0,1\}^{j-k}\\ r_1|0\neq r_2|0}} 1|^{(1+\epsilon)/2}.\end{aligned}$$

There are 2^k possible values for r and less than $2^{2(j-k)}$ values for the couple (r_1, r_2), thus

$$\mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] \leq 2^{-jp(1+\epsilon)} K \sum_{k=0}^{j-1} \mathbb{E}\left[W^{p(1+\epsilon)}\right]^k \mathbb{E}\left[W^p\right]^{(j-k)(1+\epsilon)} 2^k 2^{(j-k)(1+\epsilon)}.$$

Since $2^{-j\tau(p)} = 2^{-jp}2^j\mathbb{E}\left[W^p\right]^j$

$$\mathbb{E}\left[|Y|^{\frac{1+\epsilon}{2}}\right] \leq K2^{-j(1+\epsilon)\tau(p)}\sum_{k=0}^{j-1} 2^{-k\tau(p(1+\epsilon))}2^{k(1+\epsilon)\tau(p)}. \tag{54}$$

Let us now take care of the diagonal terms of X (51). First, we write

$$D^{\frac{1+\epsilon}{2}} \leq 2^{-jp(1+\epsilon)}\sum_{r\in\{0,1\}^j}\prod_{i=1}^{j} W_{r|i}^{p(1+\epsilon)}|Z^{(r)}|^{1+\epsilon},$$

and using the $\mathbb{E}\left[|Z|^{1+\epsilon}\right] < \infty$ we deduce that

$$\mathbb{E}\left[D^{\frac{1+\epsilon}{2}}\right] \leq C2^{-jp(1+\epsilon)}2^j\mathbb{E}\left[W^{p(1+\epsilon)}\right]^j = C2^{-j\tau(p(1+\epsilon))}. \tag{55}$$

Merging (54) and (55) into (52) leads to

$$\mathbb{E}\left[|X|^{1+\epsilon}\right] \leq K2^{-j(1+\epsilon)\tau(p)}\sum_{k=0}^{j} 2^{-k\tau(p(1+\epsilon))}2^{k(1+\epsilon)\tau(p)},$$

and since $\mathbb{E}\left[|\mathcal{M}_j(p)|^{1+\epsilon}\right] = \mathbb{E}\left[|X|^{1+\epsilon}\right]$, it completes the proof. ☐

APPENDIX B: LEMMA USED FOR THE PROOF OF THEOREM ??

Lemma 3. *Let $f : [0,1] \to \mathbb{R}$ be some Borel function whose support is included in $I_{a,\overline{r}} = [\frac{\overline{r}}{2^a}, \frac{(\overline{r}+1)}{2^a}]$ for $r \in \{0,1\}^a$, $a \geq 0$. Then*

$$\langle \mu_\infty, f\rangle = 2^{-a}\left(\prod_{i=1}^{a} W_{r|i}\right)\left\langle \overline{\mu}_\infty^{(r)}, \tilde{f}\right\rangle \tag{56}$$

where $\tilde{f}(x) = f(2^{-a}(x+\overline{r}))$ and $\overline{\mu}_\infty^{(r)}$ is a cascade measure on $[0,1]$ measurable with respect to the sigma field $\sigma\{W_{rr'}, r' \in \{0,1\}^{a'}, a' \geq 1\}$.

Proof. The scaling relation (56) is easily obtained, by the definition of the measure μ_∞, if f is the characteristic function of some interval $I_{a+a',\overline{rr'}}$ where $r' \in \{0,1\}^{a'}$, $a' \geq 0$. This relation extends to any Borel function f by standard arguments of measure theory. ☐

Lemma 4. *Let $h : [0,1] \to \mathbb{R}$ be a piecewise continuous, non zero, function. Then $\mathbb{E}\left[|\langle \mu_\infty, h\rangle|^p\right] > 0$ for all $p > 0$.*

Proof. By contradiction, assume that for some $p>0$, $\mathbb{E}\left[|\langle\mu_\infty,h\rangle|^p\right]=0$. Hence $\langle\mu_\infty,h\rangle=0$, $\mathbb{P}$-almost surely. But using Lemma 3,

$$\begin{aligned}0=\langle\mu_\infty,h\rangle&=\left\langle\mu_\infty,h1_{[0,1/2]}\right\rangle+\left\langle\mu_\infty,h1_{(1/2,1]}\right\rangle\\&=\frac{1}{2}W_0\left\langle\overline{\mu}_\infty^{(0)},h^{(0)}\right\rangle+\frac{1}{2}W_1\left\langle\overline{\mu}_\infty^{(1)},h^{(1)}\right\rangle,\end{aligned}$$

where $h^{(0)}(\cdot)=h(2^{-1}\cdot)$, $h^{(1)}(\cdot)=h(2^{-1}(\cdot+1))$ and $\overline{\mu}_\infty^{(0)}$, $\overline{\mu}_\infty^{(1)}$ are independent cascade measures on $[0,1]$. Thus we deduce $W_0\left\langle\overline{\mu}_\infty^{(0)},h^{(0)}\right\rangle=-W_1\left\langle\overline{\mu}_\infty^{(1)},h^{(1)}\right\rangle$ almost surely, and since $W>0$ this shows that with probability one the two independent variables $\left\langle\overline{\mu}_\infty^{(0)},h^{(0)}\right\rangle$ and $\left\langle\overline{\mu}_\infty^{(1)},h^{(1)}\right\rangle$ vanish simultaneously. This is only possible either, if they both vanish on a set of full probability, or if they both vanish on a negligible set. Assume the latter, then the following identity holds almost surely

$$\frac{\left\langle\overline{\mu}_\infty^{(0)},h^{(0)}\right\rangle}{\left\langle\overline{\mu}_\infty^{(1)},h^{(1)}\right\rangle}=-\frac{W_1}{W_0}$$

where the variables on right and left hand side are independent. These variables must be constant, which is excluded by the assumption $\mathbb{P}(W=1)<1$ (recall (5)).

Thus we deduce that the variables $\left\langle\overline{\mu}_\infty^{(i)},h^{(i)}\right\rangle$ are almost surely equal to zero. Hence:

$$\mathbb{E}\left[\left|\left\langle\mu_\infty,h^{(i)}\right\rangle\right|^p\right]=0,\ \text{for } i=0,1.$$

Iterating the argument we deduce the following property: for any $j\geq 0$ and $k\leq 2^j-1$, if we define a function on $[0,1]$ by $h^{(j,k)}(x)=h(2^{-j}(x+k))$ we have

$$\mathbb{E}\left[\left|\left\langle\mu_\infty,h^{(j,k)}\right\rangle\right|^p\right]=0.$$

This is clearly impossible if we choose j,k such that h remains positive (or negative) on $[k2^{-j},(k+1)2^{-j}]$. By the assumptions on h one can find such an interval, yielding to a contradiction. □

Lemma 5. *We have*

$$\mathbb{E}\left[\left|\mathcal{S}_{\tilde{\mu},g}-\mathbb{E}\left[\mathcal{S}_{\tilde{\mu},g}\right]\right|^{1+\epsilon}\right]\leq C2^{j\chi}\mathbb{E}\left[\left|\mathcal{S}_{\mu,g}(j,p)\right|^{1+\epsilon}\right]$$

where C is a constant that depends only on ϵ.

Proof. The proof is the exact same proof as for Lemma 1. □

Lemma 6. *For any $\epsilon > 0$ small enough we have,*

$$\mathbb{E}\left[|\mathcal{S}_{\mu,g}(j,p)|^{1+\epsilon}\right] \leq K 2^{-j(1+\epsilon)\tau(p)} \sum_{k=0}^{j} 2^{-k\tau(p(1+\epsilon))} 2^{k(1+\epsilon)\tau(p)},$$

where K is a constant that depends only on p and ϵ.

Proof. The proof basically follows the same lines as the proof of Lemma 2. The only difficulty, compared to this latter proof, comes from the fact that the quantity $\langle \mu_\infty, g_{j,k}\rangle$ a priori involves several nodes of level j of the M-cascade. We have to reorganize the sum (43).

Since we are interested in the limit $j \to +\infty$, we can suppose, with no loss of generality that $j > J$. In the following, we note $1^{(n)}$ the n-uplet

$$1^{(n)} = 11\ldots1, \quad \text{where the 1 is repeated } n \text{ times.}$$

The partition function (43) can be written $\mathcal{S}_{\mu,g}(j,p) = \sum_k |\left\langle \mu_\infty, g_{j,\overline{k}}\right\rangle|^p$, where the sum is over $k \in \{0,1\}^j$ such that $k_l = 0$ for some $l \leq j - J$. The sum can be regrouped in the following way, where $a+1$ denotes the position of the last 0 in the $j - J$ first components of k:

$$\mathcal{S}_{\mu,g}(j,p) = \sum_{a=0}^{j-J-1} \sum_{\substack{r\in\{0,1\}^a \\ q=r0}} \sum_{s\in\{0,1\}^J} \left|\left\langle \mu_\infty, g_{j,\overline{q1^{(j-J-1-a)}s}}\right\rangle\right|^p .$$

We set

$$X_{a,s} = \sum_{\substack{r\in\{0,1\}^a \\ q=r0}} \left|\left\langle \mu_\infty, g_{j,\overline{q1^{(j-J-1-a)}s}}\right\rangle\right|^p \tag{57}$$

and consequently

$$\mathcal{S}_{\mu,g}(j,p) = \sum_{a=0}^{j-J-1} \sum_{s\in\{0,1\}^J} X_{a,s}.$$

Actually, a exactly corresponds to the level of the "highest" node that is common for dyadic intervals in the support of $g_{j,\overline{q1^{(j-J-1-a)}s}}$. Indeed, let us prove that

$$a \geq 0,\ \forall s \in \{0,1\}^J, \quad \text{Supp } g_{j,\overline{q1^{(j-J-1-a)}s}} \subset I_{a,\overline{r}}, \tag{58}$$

where $q = r0$. Indeed, according to (42), the support of $g_{j,\overline{q1^{(j-J-1-a)}s}}$ is included in $[2^{-j}\overline{q1^{(j-J-1-a)}s}, 2^{-j}\overline{q1^{(j-J-1-a)}s} + 2^{-(j-J)}]$. Then,

$$\begin{aligned} 2^{-j}\overline{q1^{(j-J-1-a)}s} &= 2^{-a}\overline{r} + \sum_{i=a+2}^{j-J} 2^{-i} + 2^{-j}\overline{s} \\ &= 2^{-a}\overline{r} + 2^{-a-1} - 2^{-(j-J)} + 2^{-j}\overline{s}. \end{aligned}$$

Since $\overline{s}$ varies in $[0, 2^J - 1]$, and $a \leq j - J - 1$, it is easy to show that

$$0 \leq 2^{-a-1} - 2^{-(j-J)} + 2^{-j}\overline{s},$$

and

$$2^{-a-1} + 2^{-j}\overline{s} \leq 2^{-a},$$

which proves (58).

We are now ready to compute the upper bound for $\|\mathcal{S}_{\mu,g}(j,p)\|_{L^{1+\epsilon}(\mathbb{P})} \leq \sum_{a=0}^{j-J-1} \sum_{s\in\{0,1\}^J} \|X_{s,a}\|_{L^{1+\epsilon}(\mathbb{P})}$. Using (57), (58) and Lemma 3, we get

$$X_{a,s} = 2^{-ap} \sum_{r\in\{0,1\}^a} \left(\prod_{i=1}^{a} W_{r|i}^p \right) |\left\langle \overline{\mu}_\infty^{(r)}, g_{j,\overline{01^{(j-J-1-a)}s}} \right\rangle|^p,$$

where the $\overline{\mu}_\infty^{(r)}$ are independent cascade measures on $[0, T]$.

Let us identify $X_{a,s}$ with X as defined in Lemma 2 by (48) in which j plays the role of a and $Z^{(r)}$ of $\left\langle \overline{\mu}_\infty^{(r)}, g_{j-a,\overline{01^{(j-J-1-a)}s}} \right\rangle^p$. As in (49), we can decompose $X_{a,s}^2$ as the sum of the non diagonal terms $Y_{a,s}$ and the diagonal terms $D_{a,s}$

$$X_{a,s}^2 = Y_{a,s} + D_{a,s}. \tag{59}$$

Using the exact same development as the one we used for $\mathbb{E}\left[X^{1+\epsilon}\right]$ starting at Eq. (47), we get the bound of the non diagonal terms corresponding to (53) in which the term $\mathbb{E}\left[Z^{(rr_1)} Z^{(rr_2)}\right]$ has to be replaced by

$$\mathbb{E}\left[\left| \left\langle \mu_\infty^{(rr_1,s)}, g_{j-a,\overline{01^{(j-J-1-a)}s}} \right\rangle \right|^p \left| \left\langle \mu_\infty^{(rr_2,s)}, g_{j-a,\overline{01^{(j-J-1-a)}s}} \right\rangle \right|^p \right]$$

which can be bounded (using (44)) by $K 2^{-2(j-a)(\tau(p)+1)}$. Going on with the same arguments as in Lemma 2, we finally get, the bound for the non diagonal terms corresponding to (54)

$$\begin{aligned} \mathbb{E}\left[|Y_{a,s}|^{\frac{1+\epsilon}{2}} \right] &\leq K 2^{-j(1+\epsilon)\tau(p)} 2^{(a-j)(1+\epsilon)} \sum_{k=0}^{a-1} 2^{-k\tau(p(1+\epsilon))} 2^{k(1+\epsilon)\tau(p)} \\ &\leq K 2^{-j(1+\epsilon)\tau(p)} 2^{(a-j)(1+\epsilon)} \sum_{k=0}^{j-1} 2^{-k\tau(p(1+\epsilon))} 2^{k(1+\epsilon)\tau(p)}. \end{aligned}$$

Following the arguments in Lemma 2 for the diagonal terms, we get

$$\mathbb{E}\left[D_{a,s}^{\frac{1+\epsilon}{2}}\right] \leq 2^{-j\tau(p(1+\epsilon))}2^{a-j}. \tag{60}$$

By (59)–(60), we finally get

$$\mathbb{E}\left[|X_{a,s}|^{1+\epsilon}\right] \leq K2^{(a-j)}2^{-j(1+\epsilon)\tau(p)}\sum_{k=0}^{j}2^{-k\tau(p(1+\epsilon))}2^{k(1+\epsilon)\tau(p)}.$$

Then we write

$$\mathbb{E}\left[|\mathcal{S}_{\mu,g}(j,p)|^{1+\epsilon}\right] \leq \|\mathcal{S}_{\mu,g}(j,p)\|_{L^{1+\epsilon}(\mathbb{P})}^{1+\epsilon} \leq \left(\sum_{a=0}^{j-J-1}\sum_{s\in\{0,1\}^J}\|X_{a,s}\|_{L^{1+\epsilon}(\mathbb{P})}\right)^{1+\epsilon}$$

and the lemma follows. ☐
